Received 26 September 1989

Addition of NBD-Cl to isolated and nucleotide-depleted CF<sub>1</sub> at pH 7.5 leads to binding of 2 NBD molecules on tyrosines of CF<sub>1</sub>, one in one of the 3  $\alpha$ -subunits and one in one of the 3  $\beta$ -subunits. MgADP reduces the amount of bound NBD in  $\beta$ , but not in  $\alpha$ . Modification as a function of time is biphasic, showing an initial rapid and a slow kinetic component. MgATP represses the initial rapid phase of binding. Incubation of O-Tyr-NBD-CF<sub>1</sub> at pH 9 causes a time-dependent shift of the NBD-molecule from tyrosine to lysine. The O-Tyr-NBD-formation is an obligatory intermediate for specific N-Lys-NBD-formation. ADP reduces the formation of the lysine-bound NBD drastically.

ATP-hydrolysis, ATPase, Chloroplast, Covalent modification, Subunit labeling, NBD

## 1. INTRODUCTION

Chloroplast H<sup>+</sup>-ATPase has a molecular mass of 400 000 [1] and a subunit stoichiometry of  $\alpha_3\beta_3\gamma\delta\epsilon$ . CF<sub>1</sub> is reported to contain 4 distinct nucleotide binding sites [2], a value which often is extrapolated to 6 for the maintenance of symmetry (3 pairs of  $\alpha/\beta$ ). Three of the binding sites are well characterized by Bruist and Hammes [3]. The first site (site 1) contains tightly bound ADP which is readily exchangeable with medium nucleotides, the second one (site 2) is a tight Mg-ATP-binding site and site 3 binds nucleotides reversibly under different conditions. Catalytic sites as well as 'tight' binding sites are found to be located at the  $\beta$ -subunits or at interfaces of the  $\alpha$ - and  $\beta$ -polypeptide chains [2].

The actual substrate used by the ATPase in the hydrolysis direction is the  $\beta, \gamma$ - $\Delta$ -Mg-ATP chelate complex [4]. ATP and ADP have at least 3 points of attachment to the protein. The first one by ionic interaction of the chelated Mg<sup>2+</sup> to a negatively charged carboxyl group of the protein. The second bond is maintained by ionic interaction of the negatively charged P <sub>$\alpha$</sub>  of the nucleotide molecule [4] to a positively charged amino group of the enzyme. This group most probably is contributed by an  $\epsilon$ -amino group of a lysine [5]. The third point of interaction is an H-bridge formed by the hydroxyl residue of tyrosine to the base N<sup>1</sup> may exist [6].

**Abbreviations** NBD-Cl (NBD), 7-chloro-4-nitrobenzofurazan, DTT, dithiothreitol

The H<sup>+</sup>-ATPases from a variety of sources are inactivated by the tyrosyl group-directed reagent NBD-Cl which forms a Meisenheimer complex on C<sup>4</sup> with the tyrosyl oxygen atom [7]. Modification of a single tyrosine residue per chloroplast F<sub>1</sub> is sufficient to inactivate the enzyme completely [8,9].

In 1975 it was reported that almost exclusively the  $\beta$ -subunits of CF<sub>1</sub> were labeled by NBD-Cl [10]. Our work shows that under tyrosine-modifying conditions two NBD molecules are bound per CF<sub>1</sub>, the first in one of the three  $\alpha$ -subunits and the second in one of the three  $\beta$ -subunits. Furthermore we investigated the transfer of NBD from tyrosine to lysine on chloroplast F<sub>1</sub>. This transfer has been reported in detail by Ferguson et al. [11] for mitochondrial ATPase. The results are discussed in context with different types of nucleotide binding sites on isolated CF<sub>1</sub>.

## 2. MATERIALS AND METHODS

Chloroplast F<sub>1</sub> was isolated and stored as described by Schumann et al. [12]. Before use, CF<sub>1</sub> was collected by centrifugation, dissolved in a minimum amount of Tris/EDTA-buffer (50 mM/2 mM), pH 7.5, and passed through a Penefsky column [13].

### *Preparation of tyrosine-bound NBD (O-Tyr-NBD-CF<sub>1</sub>)*

Reactions with unlabeled NBD-Cl were initiated by addition of NBD-Cl (in ethanol, final concentration 200  $\mu$ M if not otherwise indicated) to 1.5–3  $\mu$ M CF<sub>1</sub> in Tris/EDTA-buffer, pH 7.5. Binding of NBD was followed spectrophotometrically. The amount of bound NBD was calculated using the extinction coefficient of 11 600 M<sup>-1</sup> cm<sup>-1</sup> (385 nm) [11]. Absorbance at 385 nm was usually measured against a reference cuvette containing an equal concentration of NBD-Cl in buffer (in the absence of protein). The absorbance of an equal concentration of CF<sub>1</sub> (in the absence of NBD-Cl) was subtracted. The reaction with NBD-Cl was terminated by precipitation of the enzyme with ammonium sulphate. After 10 min on ice, the precip-

itate was collected by centrifugation, redissolved in 100  $\mu$ l of Tris/EDTA, pH 7.5, and passed through a Penefsky column.

Ca-ATPase activity of the modified enzyme was measured after trypsin-activation as described by Vambutas and Racker [14] in a medium containing 20 mM Tris, pH 8, 5 mM  $\text{CaCl}_2$ , 5 mM  $^{32}\text{P}$ -labeled ATP and 10  $\mu$ g modified  $\text{CF}_1$  (final volume 0.5 ml).

$^{32}\text{P}$ -Labeled ATP was prepared by a method of Avron [15].

Binding of  $^{14}\text{C}$ -labeled NBD-Cl was accomplished in the same way as described for unlabeled NBD. [ $^{14}\text{C}$ ]NBD was purchased from CEA, France (sp. act. 4.81 GBq/mmol). After removing excess label by centrifugation according to Penefsky [13], the NBD-*O*-tyrosyl group had to be stabilized before transferring the protein to the gel. This was achieved by conversion of the nitro group of the NBD into an amino group by chemical reduction with sodium dithionite [17]. The subunit distribution of the label was studied in SDS-polyacrylamide gels (gradient gel, 17.5–22.5% polyacrylamide), after staining with Coomassie blue. The subunit bands of  $\text{CF}_1$  were cut out, solved in 30% alkaline  $\text{H}_2\text{O}_2$  [18] and measured by liquid scintillation counting.

#### Preparation of lysine-bound NBD (*N*-Lys-NBD- $\text{CF}_1$ )

*N*-Lys-NBD- $\text{CF}_1$  was prepared from *O*-Tyr-NBD- $\text{CF}_1$  (which was cleaned from free NBD) by adding a sufficient amount of Tris-buffer (2 M), pH 9, to increase the pH to 9 as described by Ferguson et al. [11]. The transfer of the NBD group could be followed by observing the shift in absorbance spectrum. The amount of bound NBD in this case was calculated using the absorption coefficient for *N*-NBD chromophores of  $26000 \text{ M}^{-1} \text{ cm}^{-1}$  (475 nm). In other cases (if indicated) desalted  $\text{CF}_1$  was redissolved in Tris/EDTA, free NBD-Cl was added and the reaction was followed spectrophotometrically at 475 nm.

### 3. RESULTS AND DISCUSSION

Addition of NBD-Cl to isolated  $\text{CF}_1$  at pH 7.5 leads to inactivation of  $\text{CF}_1$  which is accompanied by formation of an *O*-Tyr-NBD chromophore with an absorbance maximum at 385 nm. Since phenolic hydroxyl groups react with NBD-Cl to give a derivative with an absorbance peak at 385 nm [11] we can conclude that NBD-Cl at pH 7.5 reacts predominantly with the hydroxyl group of a tyrosyl residue in  $\text{CF}_1$ . In fig. 1, inhibition of Ca-ATPase activity of isolated  $\text{CF}_1$  by addition of NBD-Cl at pH 7.5 is shown. In this experiment we observed 85% inhibition within 30 min. As reported earlier for  $\text{F}_1$  from *E. coli* [19] and  $\text{BF}_1$  [20], inhibition of ATPase activity is completely reversible by addition of DTT. As lysine-bound NBD is not affected by thiol reagents like DTT, this reaction can be taken as a measure for the amount of bound *O*-Tyr-NBD. Using the extinction coefficient given by Ferguson et al. (see section 2) and a molecular mass of 400 000 for  $\text{CF}_1$ , we have calculated a  $\text{CF}_1$ /bound NBD ratio of 1 (pH 7.5) under conditions where the enzyme has been completely inhibited.

When *O*-Tyr-NBD- $\text{CF}_1$  was incubated at pH 9.0, a time-dependent shift in the absorbance maximum from 385 to 475 nm was observed. Under the employed conditions (nucleotide-depleted  $\text{CF}_1$ ), the shift was complete after 80 min (fig. 2). Precipitation with ammonium sulphate and centrifugation-elution of the protein/NBD solution (Penefsky [13]) showed that the NBD completely remained on the enzyme. In contrast

Fig. 1 Inhibition of Ca-ATPase activity by modification of  $\text{CF}_1$  with NBD-Cl at pH 7.5. 2  $\mu\text{M}$   $\text{CF}_1$  was incubated with 80  $\mu\text{M}$  NBD-Cl. Other conditions, see section 2. 100% activity = 150  $\mu\text{mol P}_i$ /mg protein per h.

to the *O*-Tyr-NBD-form, the *N*-Lys-NBD- $\text{CF}_1$  is stable and can be stored as an ammonium sulphate precipitate for more than one month.

The formation of primary amine products occurs at slightly alkaline pH (pH > 7.5). The time-course as a function of pH is shown in fig. 3. At pH 7.5, 0.2 mol NBD/mol enzyme were bound in the amine-form after 60 min, at pH 8, 1.2 mol/mol, whereas at pH 9 after the same time 2.8 NBD/ $\text{CF}_1$  can be calculated. If tyrosine residues should be modified, a pH of 7.5 or less should be strongly kept.

The slopes in fig. 3 exhibit a lag-phase which disappears after preincubation of the enzyme with NBD-Cl at pH 7.5 (fig. 4, control), showing that *O*-Tyr-NBD formation on  $\text{CF}_1$  is an obligatory intermediate for specific *N*-Lys-NBD formation. A similar result has

Fig. 2. Transfer of the NBD group from a tyrosyl oxygen to a lysyl nitrogen of isolated  $\text{CF}_1$ , followed by observing the shift in absorbance spectrum. 7.5  $\mu\text{M}$  of desalted *O*-Tyr-NBD- $\text{CF}_1$  was dissolved in 40 mM Tris/2 mM EDTA, pH 7.5. Spectra were taken before and 0, 10, 30, 50, 70, and 80 min after transfer to pH 9.

Fig. 3. Binding of NBD-Cl to lysine residues of CF<sub>1</sub>, measured by the increase in absorbance at 475 nm at 3 different pH values. Conditions, see section 2

been reported for modification of lysozyme with NBD-Cl [16]. The lysine where NBD is transferred to, belongs to a reversible nucleotide binding site, which is protected against modification by ADP. Addition of excess ADP (in the presence of Mg<sup>2+</sup> and P<sub>i</sub>) to a preparation of *O*-Tyr-NBD before the pH value of the medium is shifted to pH 9, leads to depression of formation of *N*-Lys-NBD, as shown in fig.4. After 30 min, not more than 0.16 mol NBD were bound to lysine per mol of CF<sub>1</sub> in presence of ADP, whereas 1.2 mol/mol CF<sub>1</sub> were bound in the control.

In a previous paper we reported, that 2 mol NBD/mol CF<sub>1</sub> could be found on tyrosine residues if the nucleotide-depleted enzyme was used [9]. Modification of CF<sub>1</sub> at pH 7.5 as a function of time is biphasic, indicating that at least two different tyrosines per CF<sub>1</sub> bind NBD-Cl. The first NBD binds with a pseudo-first-order rate of 0.2 min<sup>-1</sup>, the second one with 0.06 min<sup>-1</sup>. Addition of excess ADP suppresses the second slow phase of binding and addition of excess Mg-ATP suppresses the first fast phase of binding, indicating two different sites of NBD-interaction on CF<sub>1</sub> [9].

In table 1 Ca-ATPase activity of isolated CF<sub>1</sub> pretreated at pH 7.5 with NBD-Cl plus/minus nucleotides is shown. Presence of Mg-ATP during the incubation reduces the inhibition only slightly, after 20 min 78% of inhibition could be observed. Presence of ADP, however, led to protection of ATPase against inactivation.

From these results we conclude that the fast reachable site to which NBD is bound may be identical to the tight Mg-ATP-binding site which has no catalytic function (site 2, Bruist and Hammes [3]). Feierabend and

Fig.4 Transfer of the NBD group from a tyrosyl to a lysyl group, followed by the increase in absorbance at 475 nm after a pH shift from 7.5 to 9, in absence (control) or in presence of 2 mM ADP and 10 mM P<sub>i</sub>. Preincubation time was 40 min

Schumann [21] found that this site has structural functions only. This would explain why Mg-ATP is not able to protect the enzyme against loss of activity. The second tyrosine which can be protected by ADP against NBD binding may be localized within or near a catalytically active site.

Using [<sup>14</sup>C]NBD-Cl we found that the latter (slow) NBD is bound to a  $\beta$ -subunit of CF<sub>1</sub> whereas the fast binding NBD interacts with the  $\alpha$ -subunit (table 2). In table 2 furthermore is shown that Mg-ADP is able to decrease the label in the  $\beta$ -subunits, but not in  $\alpha$  (line 3). ADP without Mg<sup>2+</sup> is not able to decrease the amount of bound NBD (line 2).

Our results lead to the conclusion that the NBD-binding tyrosine on the  $\beta$ -subunit may belong to site 1, the one which according to Bruist and Hammes [22] is a regulatory one but with regard to Wu and Boyer [23] has catalytic activity. As site 3 binds ADP in absence of divalent cations too, NBD binding to this site should be suppressed in the presence of ADP without MgCl<sub>2</sub>.

Reaction of 1 NBD with a tyrosine on CF<sub>1</sub> which prevented binding of nucleotides to the catalytic site and abolished ATPase activity, was already reported by Cantley and Hammes in 1975 [8]. The authors determined 1.6 NBD/CF<sub>1</sub> (pH 8) using an extinction coefficient of 10 700 M<sup>-1</sup>·cm<sup>-1</sup> at 400 nm. They further assumed 3 NBD-reactive  $\beta$ -tyrosines according to the subunit-stoichiometry of  $\beta_3$  [24]. Deters et al. [10] have reported that <sup>3</sup>H-labeled NBD was bound exclusively to the  $\beta$ -subunits of CF<sub>1</sub>. This difference to our results may be explainable by the different experimental conditions. The authors used CF<sub>1</sub> which was not depleted from nucleotides, and they worked at pH 8 using very long incubation times. During the preparation of this work Ceccarelli et al. [25] published results about modification of isolated CF<sub>1</sub> with NBD-Cl. They found 1.2 mol *O*-Tyr-NBD/mol CF<sub>1</sub> bound to  $\beta$ -subunits and that Tyr- $\beta$ -328 which is homologous to Tyr- $\beta$ -311

Table 1

Ca-ATPase activity of isolated CF<sub>1</sub> pretreated with NBD-Cl at pH 7.5 ± nucleotides

Incubation time (min)	μmol P <sub>i</sub> /mg CF <sub>1</sub> per h					
	control	%	+ ATP	%	+ ADP	%
0	447.3	100	524.2	100	549.0	100
2	117.6	26	208.5	40	355.5	75
10	56.1	13	169.0	32	341.5	57
20	48.3	11	114.3	22	353.0	64

CF<sub>1</sub> (3 μM) was pretreated with 80 μM NBD-Cl at pH 7.5 in presence or absence of the indicated nucleotides which were 2 mM. Experimental conditions, see section 2

Table 2

Quantitative evaluation of <sup>14</sup>C-labeled NBD bound to separated subunits of CF<sub>1</sub>

Conditions	mol [ <sup>14</sup> C]NBD/mol CF <sub>1</sub>		
	total CF <sub>1</sub>	subunits	
		α	β
control	1.7	0.8	0.9
+ 2 mM ADP	1.6	0.8	0.8
+ 2 mM ADP + 5 mM MgCl <sub>2</sub>	1.1	0.8	0.3

500 μg nucleotide-depleted CF<sub>1</sub> was incubated at pH 7.5 with 400 μM <sup>14</sup>C-labeled NBD-Cl for 1 h. Experimental conditions are described in section 2

(MF<sub>1</sub>) is that residue which reacts with NBD-Cl at pH 7.5. This tyrosine is neither the one proposed to belong to the catalytic site (identified by covalently bound 2-azido-ADP, derived from 2-azido-ATP) nor the one which contributes to the non-catalytic binding site [26]. Ceccarelli et al. worked with CF<sub>1</sub> in presence of 1 mM ATP; this explains that they found one NBD/CF<sub>1</sub> (only the one bound to β-subunit). We are now employing the positions of the NBD-binding tyrosines under nucleotide-depleted conditions.
